

In a study of wild bears, researchers measured the length, in inches (in.) of 143 wild bears that ranged in age from newborn to 15 years old. The data was used to make the histogram shown.

- How many bears are between 45 and 50 inches long?
10 bears
- Which single range of length has the most bears?
60 – 65 inches
- What is the smallest possible length of a bear in this data set?
35 inches
- Are there more bears measuring less than 65 inches or more than 65 inches?
There are more bears measuring less than 65 inches.
- If bears older than 15 were added to the sample, hypothesize what would happen to the spread of the data.
I think the data would skew more to the right.
- Mark an “M” above the bar that contains the median.
Shown on histogram

An earthworm farmer set up several containers of a certain species of earthworm so he could learn about their lengths. Lengths of earthworms provide information about their ages. The farmer measured the lengths of earthworms in one container. The farmer measured the earthworms in millimeters then created a histogram from the data.

7. Is it possible for the sample to contain an earthworm measuring more than 100 mm?
No
8. More than half of the earthworms measure less than 30 millimeters.
9. How many data pieces are in the histogram?
25 data points
10. What single range of lengths has the most earthworms?
20 – 30 millimeters
