Summary of Quarter 2 Instructional Topics

Topics are linked to the SCPS Frameworks site. ***Bolded benchmarks are assessed on the current quarter assessment. The benchmarks that are not in bold may be assessed in the following quarter, unless otherwise stated.***

Topic 3 - Transformations	With 4 lessons over 15 recommended instructional days, this topic covers benchmarks MA.912.GR.2.1, MA.912.GR.2.3, MA.912.GR.2.2, In Topic 3, students formalize their early understanding of slides, flips, and turns by studying rigid transformations of the plane—translations, reflections, rotations, and glide reflections. These transformations preserve distance and angle measures, and each is defined by a specific set of characteristics, such as the center and angle in a rotation.
---------------------------	--

	Students learn to identify missing elements in transformation problems—such as the image, the pre-image, or the transformation itself—and explore compositions of transformations. They discover that a sequence of rigid motions results in another rigid motion, such as a glide reflection formed by a reflection followed by a translation. A key conceptual point is that figures do not "move"; rather, a transformation defines a correspondence between the pre-image and image. Students also study symmetry—reflectional, rotational, and point symmetry—as the result of transformations that map a figure onto itself. Throughout the topic, students confront common misconceptions and perceptual challenges, such as recognizing reflections when the line of reflection is not vertical or interpreting symmetry in complex images. These foundational ideas prepare students for later topics, where they will explore non-rigid transformations and apply transformations to algebraic and geometric contexts.
Topic 4- Triangle Congruence	With 4 lessons over 18 recommended instructional days, this topic covers benchmarks MA.912.GR1.2, MA.912.GR.1.6, MA.912.GR.1.3, MA.912.GR.2.3, MA.912.GR.2.6 Topic 4 focuses on congruence and transformations that produce congruent figures. Students begin by defining congruence and congruence transformations, using examples to determine whether figures are congruent. The topic then introduces triangle congruence theorems—such as SSS, SAS, ASA, and AAS—and shows how they can be used to prove that two triangles are congruent based on given side and angle information. Students apply these theorems to identify corresponding parts, determine missing measurements, and justify congruence between figures. Special attention is given to isosceles and equilateral triangles, where students explore unique angle and side relationships and how these relate to congruence and transformations. They also learn the Hypotenuse-Leg (HL) Theorem for right triangles. The topic concludes with students analyzing overlapping triangles, identifying congruent parts, and applying appropriate congruence theorems in more complex figures.
Topic 5- Relationships in Triangles	With 5 topics over 16 recommended instructional days, this topic covers benchmarks MA.912.GR.1.1, MA.912.GR.1.3, MA.912.GR3.3., MA.912.GR.5.2, MA.912.GR.5.3, MA.912.GR.6.3 <i>MA.912.GR.5.2, MA.912.GR.5.3, MA.912.GR.6.3 will not be tested on benchmark assessment 2</i> In Topic 5, students explore the special points of concurrency in triangles—perpendicular bisectors, angle bisectors, medians, and altitudes. They investigate the properties of these segments and the points they form: the circumcenter, incenter, centroid, and orthocenter. Students learn how perpendicular and angle bisectors relate to loci of points equidistant from sides or vertices, leading to proofs of the Perpendicular Bisector and Angle Bisector Theorems. Students discover that the centroid is the triangle’s center of gravity and use coordinate geometry to find the coordinates of triangle centers, including the orthocenter. The topic then shifts to the relationship between side lengths and angle measures in triangles, allowing students to compare angles based on side lengths without direct measurement. The topic concludes with the introduction of the Hinge Theorem and its converse, which help students compare side lengths in triangles based on the size of included angles. These concepts deepen students’ understanding of triangle properties and geometric reasoning.
